Working principle

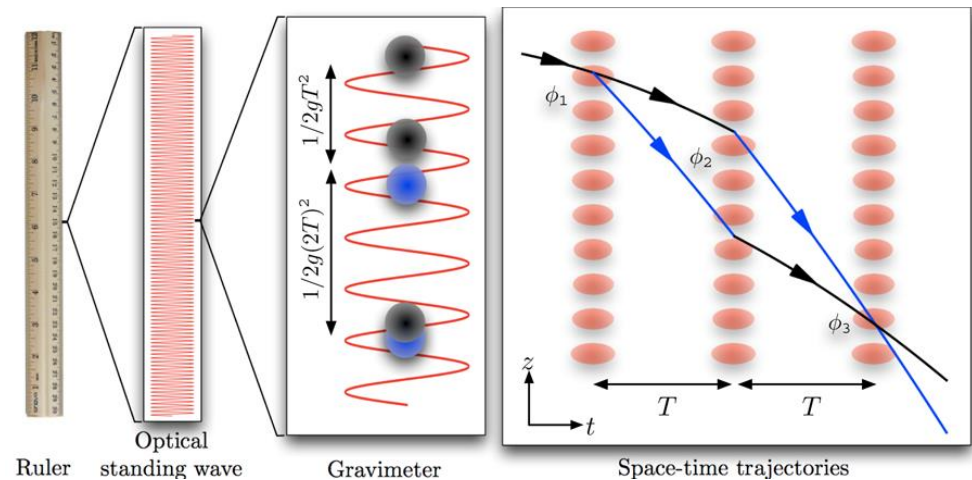

Photon momentum transfer

- Raman transition
- Bragg diffraction

Phase read-out

- Fluorescence
- Absorption image

- The interferometer phase
 - The atomic motion against the ruler
 - $\phi_1 - 2\phi_2 + \phi_3$
 - Sensitive to acceleration

J. E. Debs, Ph.D. Thesis, The Australian National University (2012)

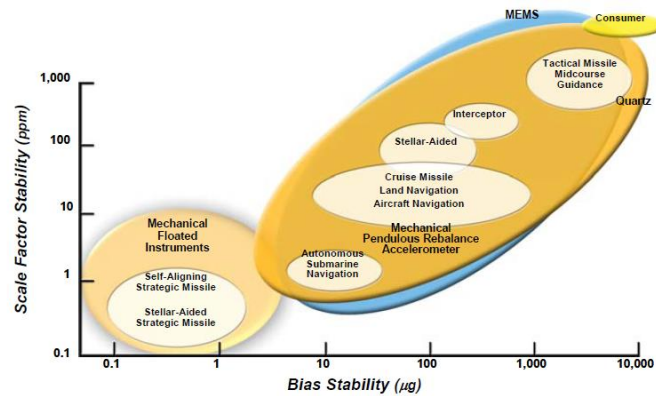

Cold atom interferometer Performance

Accuracy: $6.7 \text{ pg} @ 2.6 \text{ s}$

M. Kasevich, Stanford, 2014

IO = Integrated Optics

RTO-EN-SET-116(2010)

Sagnac effect

- Sagnac interferometer is sensitive to rotation

Pictures: <https://www.mezzacotta.net/100proofs/archives/190>

Sagnac effect

- Sagnac interferometer phase is presented [1]

$$\Phi_{\text{Sagnac}} = \frac{2E}{\hbar c^2} \boldsymbol{\Omega} \cdot \mathbf{A}$$

- Ω is the rotation, A is the area enclosed by the interferometer.
- E is the particle energy of the interfering photons or atoms
- Comparing the energy of atoms and photons

$$\frac{m_{\text{Rb}} c^2}{\hbar \omega_{633\text{nm}}} = 1.2 \times 10^{11}$$

- The scale factor of atom is huge

1. G. Tackmann *et al.*, Large-area Sagnac atom interferometer with robust phase read out. *Comptes Rendus Physique* **15**, 884-897 (2014).

An example of atom gyroscope

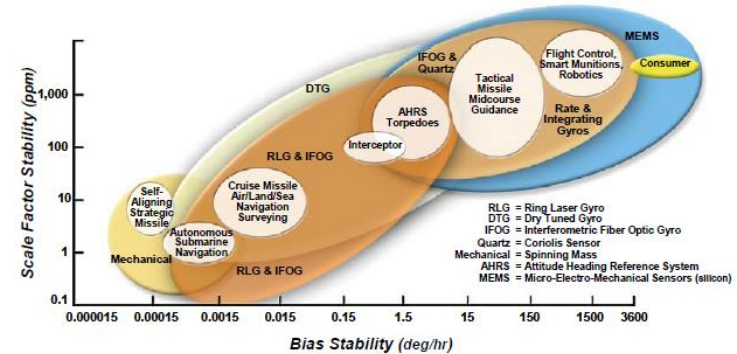

Free-space Cs fountain type: $L \sim 60 \text{ cm}$,
 $T \sim 200 \text{ ms}$

Two-photon Raman transition between clock state

Stability 0.00006 deg/hr , rate 3.75 Hz

- Current and future gyro technologies

RTO-EN-SET-116(2010)

What could be further improvement

Typical atom interferometer

- Free space
 - Free-falling atoms
 - Expanding atom
- Cold atoms

It might be desired

- Waveguide
 - Hold atoms
- Ultracold atoms (BEC)

What we expect

Longer coherence time in a compact system size

Pros/Cons of using BEC

Advantage

- Colder and denser
 - Less dispersive
 - Longer measurement time in a compact system
 - Higher signal contrast

Disadvantage

- System complexity
 - Lower duty cycle
 - Higher cost
 - Less robust
 - Less atom number
- Denser
 - Interaction effect is pronounced

Pros/Cons of using waveguide

Advantage

- Confinement
 - Less dispersive
 - Longer measurement time in a compact system
 - Higher signal contrast

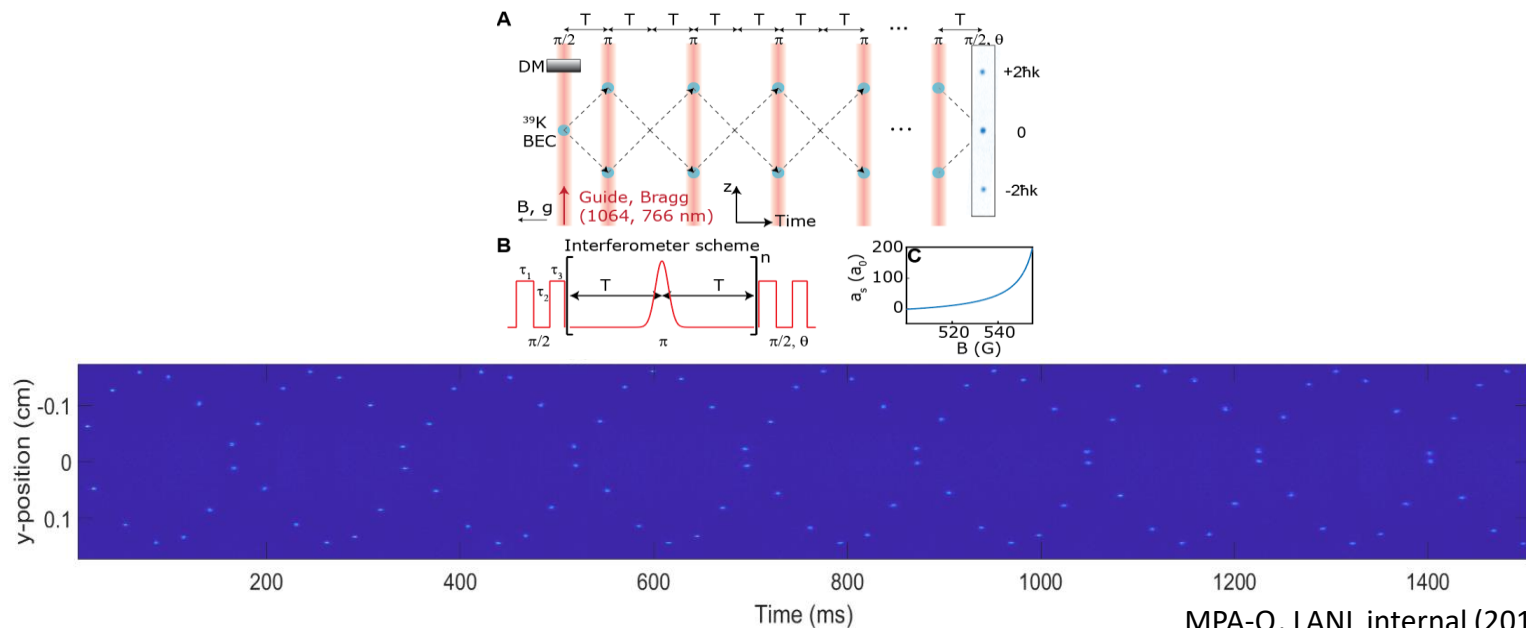

Disadvantage

- System complexity
 - Less robust
 - Waveguide fluctuation, curvature
- Confinement
 - Inhomogeneous dephasing

A waveguide BEC interferometer at LANL

- Waveguide: Loosely focused optical dipole trap
- BEC: ^{39}K $|F, m_F\rangle = |1, -1\rangle$
- Multiple-loop scheme

Overcome the disadvantages and maximize the benefits of waveguide BEC interferometer.

MPA-Q, LANL internal (2019)

Experimental goals for waveguide BEC interferometer

Overcome Disadvantages

- Dense atoms
 - Interaction effect is pronounced
- Confinement effect
 - Inhomogeneous dephasing

Tools

- Non-interacting condensate
 - Reduce wave packet dispersion
 - Reduce collisional loss and dephasing
- New pulse scheme
 - Multiple-loop atom interferometer
 - Increase available coherence time

Disadvantage1: Interacting BEC

- Gross-Pitaevskii Eq. of the condensate wave function

$$\left(-\frac{\hbar^2 \nabla^2}{2m} + V_{\text{ext}}(\mathbf{r}) + g \phi^2(\mathbf{r}) \right) \phi(\mathbf{r}) = \mu \phi(\mathbf{r}).$$

$$g = \frac{4\pi\hbar^2 a}{m}.$$

Two-body collisions characterized by the s-wave scattering length

- Solution:** S-wave scattering length is tunable by magnetic field.

- ^{39}K $|1,-1\rangle \rightarrow |1,-1\rangle$ s-wave scattering length [1]

$$a_s = -29a_0 \left[1 + \frac{56 \text{ G}}{B - 562.2 \text{ G}} \right]$$

- Evaporation at $a_s > 300a_0$ and get the condensate atoms

[1] C. D'Errico *et al.*, Feshbach resonances in ultracold ^{39}K . *New Journal of Physics* **9**, 223-223 (2007)

Disadvantage2: Confinement effect

Single-loop

- More inhomogeneous dephasing as atoms move farther.

Solution: Multiple-loop

- It sustains longer coherence time
- Deploy dynamic decoupling

Phase gradient of the wave packet

$$\frac{d\phi}{dz} \propto (\omega_z T)^2 \text{ for } \frac{\pi}{2} \xleftrightarrow{T} \pi \xleftrightarrow{T} \frac{\pi}{2}$$

$$\propto (\omega_z T)^4 \text{ for } \frac{\pi}{2} \xleftrightarrow{T} \pi \xleftrightarrow{2T} \pi \xleftrightarrow{T} \frac{\pi}{2}$$

$$\propto (\omega_z T)^4 \text{ for } \frac{\pi}{2} \xleftrightarrow{T} \pi \xleftrightarrow{2T} \pi \xleftrightarrow{2T} \pi \xleftrightarrow{T} \frac{\pi}{2}$$

^{39}K BEC generation

Vacuum chamber

Laser cooling

Laser trapping

Atom transport

Forced evaporation

Vacuum chamber (top view)

Laser cooling

- High pressure (HP) D2 MOT is $2\sim 3\text{ mK}$, pushed to the low pressure (LP) chamber.
- LP D2+D1 hybrid MOT: $\sim 60\text{ }\mu\text{K}$, $8 \times 10^{10}/\text{cm}^3$
- LP D1 gray molasses: $6\text{ }\mu\text{K}$, $8 \times 10^{10}/\text{cm}^3$

1550 nm laser trapping

- Magnetic trap ($\sim 150 \text{ G/cm}$) holds atoms
- 1550nm Dipole trap ($w_0 = 35 \mu\text{m}$, $T \sim 770 \mu\text{K}$) is overlapped.
- The dipole trap captures the atoms
 - $\sim 10^6$ atoms, spin polarized to $|1, -1\rangle$
 - $T \sim 15 \mu\text{K}$, $\sim 10^{11}/\text{cm}^3$
- The atoms are transferred to the glass cell.
 - Spin polarization is maintained by Earth's magnetic field
 - Translation stage (Newport XML350) moves for 1 s.
 - No atom loss, No heating
 - Axial sloshing is observed after translation.
 - $2\pi \times \omega_z = 36 \text{ Hz}$

Forced evaporation cooling

- Set $a_s \sim 200a_0$ and reduce 1550 nm beam power for 1 s.
- The atoms are transferred to 1064 nm cross dipole +waveguide.
 - Dimple effect
 - $w_0 = 100 \mu m, T \sim 500 \mu K$
- Set $a_s \sim 0a_0$ and increase 1064 nm beam power for 0.2 s.
 - Adiabatic compression
- Set $a_s \sim 400a_0$ and forced evaporation for 5 s.
 - $I(t) = \left(1 + \frac{t}{0.25 s}\right)^{-1.45}$
- BEC is formed, $2\pi \times (77, 100, 12) Hz$
- Cross dipole power is further down to 0.
 - 1D quasi condensate, $2\pi \times (77, 100, 2.9) Hz$

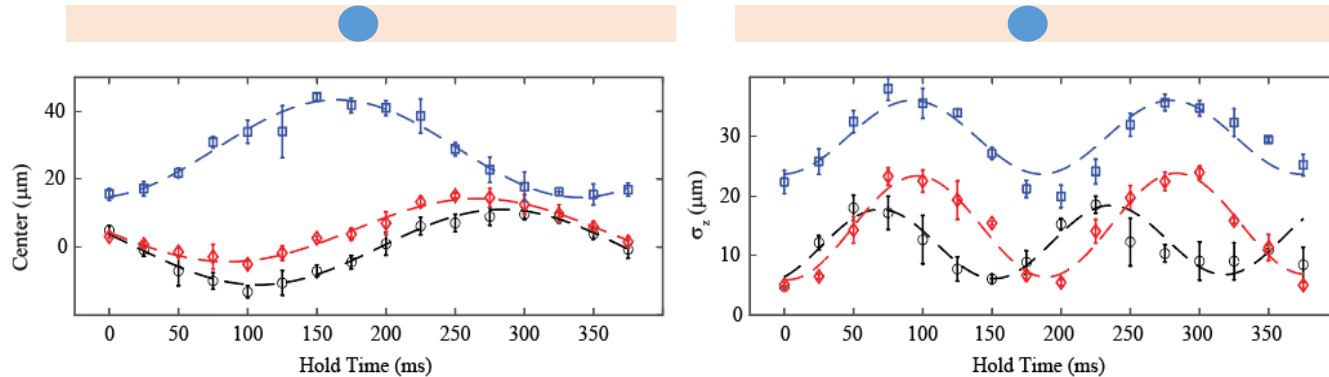

Interaction tuning of the condensate

- Absorption Images after 16 ms of time-of-flight.
 - Repulsive interaction expands the wave packet

Compressional mode

- BEC is formed, $2\pi \times (77, 100, 12) \text{ Hz}$
- Cross dipole power is further down to 0.
 - 1D quasi condensate, $2\pi \times (77, 100, 2.9) \text{ Hz}$

- [black, red, blue], $a_s = [-2.5, 0.7, 150]a_0$
- $\frac{\omega_c}{\omega_z} = [2.1(2), 1.8(1), 1.7(2)]$, agrees with theory [1].

[1] E. Haller *et al.*, Realization of an Excited, Strongly Correlated Quantum Gas Phase. *Science* **325**, 1224-1227 (2009).

Result: Multiple-loop scheme

- Momentum is given by Bragg diffraction
- Small amplitude, many round-trip
 - Minimize inhomogeneous dephasing from confinement potential
 - Dynamic decoupling of noise: $\phi_{laser} = \phi_{\pi/2} + 2 \sum_{i=1}^{n=even} (-1)^i \phi_{\pi} - \phi_{\pi/2, \theta}$
- Zero s-wave scattering length
 - Reduce collision induced dephasing and loss

Interferometer fringe

- Coherence time is 900 ms for $n=400$
 - $T=1.125$ ms
 - The s-wave scattering length: $a_s = 1.7 a_0$

- Only atom loss limits more π pulse
 - Current π pulse efficiency: 99.4 % $\Rightarrow 0.994^{400} = 0.09$
 - Theory: $0.999^{2000} = 0.13$
 - 4.5 s coherence time is expected

Atom loss: collisional loss + mirror pulse

- One and two-body loss model
 - $\frac{dN_{tot}}{dn} = -aN_{tot}^2 - bN_{tot}$
 - The coefficient b : π pulse loss
 - The coefficient a : colliding BEC loss
 - The scaling law holds [1]: $a \propto a_s^2$

[1] Y. B. Band, M. Trippenbach, J. P. Burke, P. S. Julienne, Elastic Scattering Loss of Atoms from Colliding Bose-Einstein Condensate Wave Packets. *Physical Review Letters* **84**, 5462-5465 (2000).

Multiple-loop scheme boosts coherence time

n=2 case: $\frac{\pi}{2} \leftrightarrow \pi \leftrightarrow \pi \leftrightarrow \frac{\pi}{2}$

- Rapid degradation of fringe contrast
 - Confinement potential induced inhomogeneous dephasing (blue)
 - Mechanical noise of the reference frame (red)

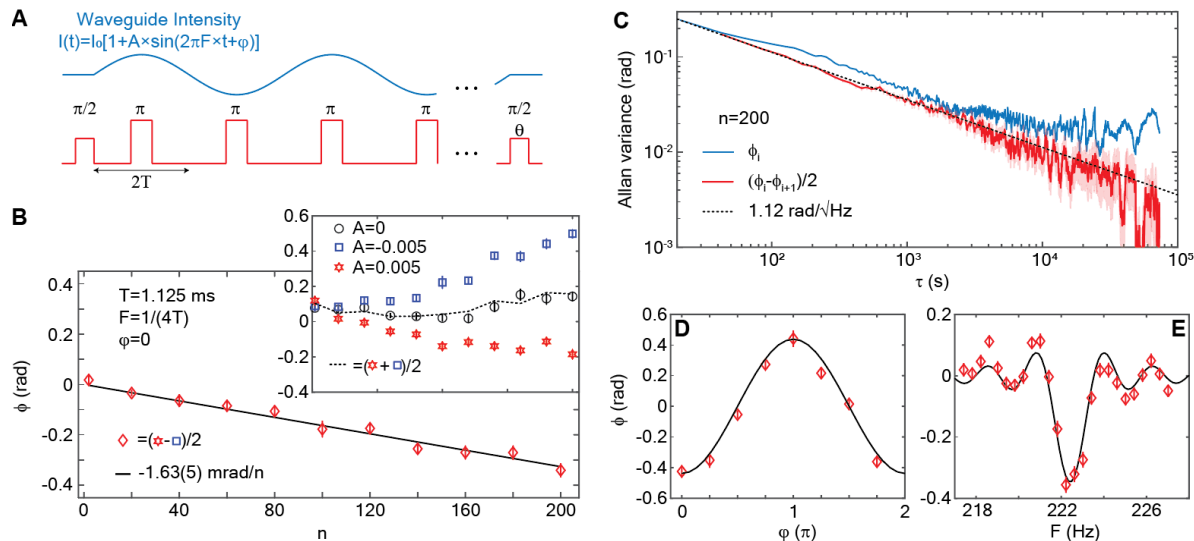

T fixed: $\frac{\pi}{2} \leftrightarrow \pi \leftrightarrow \pi \cdots \leftrightarrow \pi \leftrightarrow \frac{\pi}{2}$

- Sustained coherence over second
 - Minimize the dephasing
 - Dynamic decoupling of noise

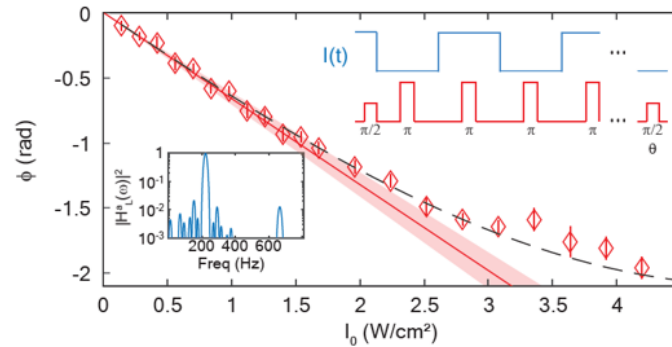

Phase sensitive AC atom interferometer: Concept proof

- $\phi_{laser} = \phi_{\pi/2} + 2 \sum_{i=1}^{n=even} (-1)^i \phi_{\pi} - \phi_{\pi/2, \theta}$
 - Cancel out DC signal.
 - Accumulate a resonant frequency signal, $F=1/(4T)$.
 - Dynamic decoupling of mechanical noise.
 - A principle of lock-in detection.

Signal measurement: AC Stark shift

- 1064 nm small beam vertically cross the waveguide.
 - Good for high gradient signal measurement.
 - The resulting dynamic polarizability from the fit: $\alpha_{1064\text{ nm}} = 620(40) \text{ a.u.}$
 - Shows a good agreement with the reference value: $\alpha_{1064\text{ nm}} = 606(5) \text{ a.u.}$ [1]
